

Strong solutions to stochastic differential equations with rough coefficients

Nicolas Champagnat^{1,2,3}, Pierre-Emmanuel Jabin⁴

March 13, 2013

Abstract

We study strong existence and pathwise uniqueness for stochastic differential equations in \mathbb{R}^d with rough coefficients, and without assuming uniform ellipticity for the diffusion matrix. Our approach relies on direct quantitative estimates on solutions to the SDE, assuming Sobolev bounds on the drift and diffusion coefficients, and L^p bounds for the solution of the corresponding Fokker-Planck PDE, which can be proved separately. This allows a great flexibility regarding the method employed to obtain these last bounds. Hence we are able to obtain general criteria in various cases, including the uniformly elliptic case in any dimension, the one-dimensional case and the Langevin (kinetic) case.

MSC 2000 subject classifications: 60J60, 60H10, 35K10

Key words and phrases: stochastic differential equations; strong solutions; pathwise uniqueness; Fokker-Planck equation; rough drift; rough diffusion matrix; degenerate diffusion matrix; maximal operator.

1 Introduction

We investigate the well posedness of the Stochastic Differential Equation (SDE) in \mathbb{R}^d , $d \geq 1$,

$$dX_t = F(t, X_t) dt + \sigma(t, X_t) dW_t, \quad X_0 = \xi, \quad (1.1)$$

where $F : \mathbb{R}_+ \times \mathbb{R}^d \rightarrow \mathbb{R}^d$ and $\sigma : \mathbb{R}_+ \times \mathbb{R}^d \rightarrow \mathbb{R}^d \times \mathbb{R}^r$ are Borel measurable functions, $(W_t, t \geq 0)$ is a r -dimensional standard Brownian motion on some given complete filtered probability space $(\Omega, (\mathcal{F}_t)_{t \geq 0}, \mathbb{P})$, and ξ is a \mathcal{F}_0 -measurable random variable.

When σ and F are bounded, it is standard to deduce from Itô's formula that the law $u(t, dx)$ of X_t is a (weak, measure) solution to the Fokker-Planck PDE on $\mathbb{R}_+ \times \mathbb{R}^d$

$$\partial_t u + \nabla_x \cdot (Fu) = \nabla_x^2 : (au) = \sum_{1 \leq i, j \leq d} \frac{\partial^2 (a_{ij}u)}{\partial x_i \partial x_j}, \quad u(t=0, dx) = u^0, \quad (1.2)$$

where $a = \frac{1}{2} \sigma \sigma^*$ and u^0 is the law of the initial r.v. ξ .

We first recall some classical terminology: weak existence holds for (1.1) if one can construct a filtered probability space $(\Omega, (\mathcal{F}_t)_{t \geq 0}, \mathbb{P})$, an adapted Brownian motion W and an adapted process X on this space solution to (1.1). Uniqueness in law holds if every solution X to (1.1), possibly on different probability space, has the same law, in particular if there is uniqueness of measure-valued solutions to (1.2). Strong existence means that one can find a solution to (1.1) on any given filtered probability space equipped with any given adapted Brownian motion. Finally, pathwise uniqueness means that, on any given filtered probability space equipped with any given Brownian motion, any two solutions to (1.1) with the same given \mathcal{F}_0 -measurable initial condition ξ coincide. Our goal is to study *strong existence and pathwise uniqueness* for rough σ and F , through quantitative estimates on the difference between solutions.

This question has been the object of many works aiming to improve the original result of Itô [10]. Krylov and Veretennikov [26, 27] studied the case of uniformly continuous a and bounded F , proving that only two cases are possible: either pathwise uniqueness holds, or strong existence does not hold. The question was studied again recently by Krylov and Röckner [16] and Zhang [29, 30]. All these works assume that the matrix a is uniformly elliptic, i.e. that $a(x) - c\text{Id}$ is positive definite for all x for some constant $c > 0$. The time-independent one-dimensional case was also deeply studied by Engelbert and Schmidt [7] (see also [28, 20]).

The main tools used in all the previous works are Krylov's inequality [12] and its extensions (see for example [6, 16, 17, 30]), Zvonkin's transformation [31] to remove the drift, and a priori estimates on solutions of the backward Kolmogorov equation or Fokker-Planck PDE (1.2) [26, 15, 16, 29]. Of great importance is also the result of Yamada and Watanabe [28], which proves that strong existence holds as soon as pathwise uniqueness and weak existence hold for all initial condition. Since general conditions for weak existence are well-known (see [13, 25, 23, 6, 17, 8]; see also [21] for a recent and deep study of the question), one only has to prove pathwise uniqueness to obtain strong existence. In dimension one, a key tool to prove pathwise uniqueness is the local time.

Another approach to strong existence and pathwise uniqueness was recently initiated by Le Bris and Lions in [18, 19], based on well-posedness results for the backward Kolmogorov equation. The authors define the notion of almost everywhere stochastic flows for (1.1), which combines existence and a flow property for almost all initial conditions, and give precise results in the case where $a = \text{Id}$. The general case was recently studied deeply by P.-L. Lions in [21], who reduces the question to well-posedness, L^1 norms and stability properties for two backward Kolmogorov equations; the first one associated to the SDE (1.1) and the other one obtained by a doubling of variable technique. Note that this approach does not require assumptions of uniform ellipticity for a .

We present here another approach which relies on estimates on path functionals of the difference between solutions to regularizations of (1.1). This is inspired by the method used by Crippa and De Lellis [4] to obtain an alternative proof of the results of Di Perna and Lions [5] on well-posedness for ODEs. The functional of [4] was used and adapted to obtain several extensions [11, 3] for deterministic systems (see also [22] for a study of weak uniqueness using this method). Note that other techniques exist to prove well posedness directly on characteristics of ODEs, see [9] for instance.

The quantitative estimates which we develop here let us treat separately the strong existence and pathwise uniqueness for (1.1) from the question of bounds on solutions to (1.2). The typical result presented here will hence assume that some estimate could be obtained on solutions to (1.2) (by whichever method) and conclude that strong existence and pathwise uniqueness hold provided that some bounds on σ and F in Sobolev spaces related to the bounds on u hold. The great advantage is the flexibility that one then enjoys as it is possible to choose the best method to deal with (1.2) according to any additional structure. For instance, ellipticity on σ is not required *a priori*. The second advantage of the method is its simplicity as

it relies on some direct quantitative estimates on the solutions.

To give a better idea let us present a typical result that we obtain. For existence we consider sequence of approximations to (1.1)

$$dX_t^n = F_n(t, X_t^n) dt + \sigma_n(t, X_t^n) dW_t, \quad X_0^n = \xi, \quad (1.3)$$

with the same Brownian motion W_t for any n . And we introduce the corresponding approximation for (1.2)

$$\partial_t u_n + \nabla_x \cdot (F_n u_n) = \sum_{1 \leq i, j \leq d} \frac{\partial^2}{\partial x_i \partial x_j} (a_{ij}^n(t, x) u_n(t, x)), \quad u_n(t=0, dx) = u^0, \quad (1.4)$$

with $a^n = \sigma_n \sigma_n^*$.

The next result is not the most general we obtain, but it does not require any additional definition and illustrates the type of assumptions we need.

Theorem 1.1 *Assume $d \geq 2$. One has*

- (i) *Existence: Assume that there exists a sequence of smooth $F_n, \sigma_n \in L^\infty$ such that the solution u_n to (1.4) satisfies for $1 \leq p, q \leq \infty$, with $1/p' + 1/p = 1, 1/q + 1/q' = 1$*

$$\begin{aligned} \sigma_n &\longrightarrow \sigma \text{ in } L_{t,loc}^q(L_x^p) \quad \text{and} \quad F_n \rightarrow F \text{ in } L_{t,loc}^q(L_x^p), \\ \sup_n \left(\|\nabla \sigma_n\|_{L_{t,loc}^{2q}(L_x^{2p})} + \|\nabla F_n\|_{L_{t,loc}^q(L_x^p)} + \|F_n\|_{L^\infty} + \|\sigma_n\|_{L^\infty} \right) &< \infty, \\ \sup_n \|u_n\|_{L_{t,loc}^{q'}(L_x^{p'})} &< \infty, \quad u_n \longrightarrow u \text{ in the weak-}^* \text{ topology of measures.} \end{aligned}$$

Then there exists a strong solution X_t to (1.1) and $(X_t^n - \xi, t \in [0, T])_n$ converges in $L^p(\Omega, L^\infty([0, T]))$ for all $p > 1$ to $(X_t - \xi, t \in [0, T])$, with X_t^n the solutions to (1.3). In addition, $u(dt, dx) = u(t, dx)dt$, where $u(t, \cdot)$ is the law of X_t for all $t \in [0, T]$.

- (ii) *Uniqueness: Let X and Y be two solutions to (1.1) with one-dimensional time marginals $u_X(t, x)dx$ and $u_Y(t, x)dx$ both in $L_{t,loc}^{q'}(L_x^{p'})$. Assume that $X_0 = Y_0$ a.s. and that*

$$\|F\|_{L_{t,loc}^q(W_x^{1,p})} + \|\sigma\|_{L_{t,loc}^{2q}(W_x^{1,2p})} < \infty$$

with $1/p + 1/p' = 1$ and $1/q + 1/q' = 1$. Then one has pathwise uniqueness: $\sup_{t \geq 0} |X_t - Y_t| = 0$ a.s.

We obtain better results in the one-dimensional case.

Theorem 1.2 *Assume $d = 1$.*

- (i) *The existence result of Theorem 1.1 (i) holds under the same assumptions on F_n, σ_n, u_n , except that the assumption $\sup_n \|\nabla \sigma_n\|_{L_{t,loc}^{2q}(L_x^{2p})} < \infty$ can be replaced by*

$$\sup_n \|\sigma_n\|_{L_{t,loc}^{2q}(W_x^{1/2,2p})} < \infty$$

and in the case $p = 1$, the assumption $\sup_n \|\nabla F_n\|_{L_{t,loc}^q(L_x^p)} < \infty$ must be replaced by

$$\sup_n \|\nabla F_n\|_{L_{t,loc}^q(L_x^{1+\varepsilon})} < \infty$$

for some $\varepsilon > 0$.

- (ii) *The uniqueness result of Theorem 1.1 (ii) holds true under the same assumptions on F, σ, u_X, u_Y , except that $\|\sigma\|_{L_{t,loc}^{2q}(W_x^{1,2p})} < \infty$ can be replaced by*

$$\|\sigma\|_{L_{t,loc}^{2q}(W_x^{1/2,2p})} < \infty.$$

and in the case $p = 1$, the assumption $\|F\|_{L_{t,loc}^q(W_x^{1,p})} < \infty$ must be replaced by

$$\|F\|_{L_{t,loc}^q(W_x^{1,1+\varepsilon})} < \infty$$

for some $\varepsilon > 0$.

Note that no assumption of uniform ellipticity is needed in Theorems 1.1 and 1.2, provided one can prove a priori estimates on the various solutions u_n, u_X, u_Y to (1.4) and (1.2). Note also that pathwise uniqueness is proved only for particular solutions to (1.1), so we cannot use directly the result of Yamada and Watanabe to deduce strong existence. Hence our method proves separately strong existence and pathwise uniqueness; however they use very similar techniques.

The goal of Section 2 is to give the statement of all our results. We start in Subsection 2.1 by defining the norms and Banach spaces needed to state our most general results in Subsection 2.2. Theorems 1.1 and 1.2 will then be obtained as corollaries of these general results.

Of course, as they are laws, u_n, u_X and u_Y all have bounded mass so Theorems 1.1 and 1.2 really depend on whether it is possible to obtain higher integrability for a solution of (1.2). Several situations where this can be

done will be studied in Subsection 2.3, including the uniformly elliptic, non-degenerate one-dimensional and kinetic (Langevin) cases. The conditions for strong existence and pathwise uniqueness can then be compared with the best conditions in the literature. The rest of the paper is devoted to the proofs of all the results stated in Section 2, and the organization of the rest of the paper is given in the end of Section 2.

2 Statement of the results

As usual one needs regularity assumptions on F and σ to ensure strong existence and pathwise uniqueness for (1.1). In our case, these are Sobolev norms with respect to u , defined in Subsection 2.1. Our general results are then stated in Subsection 2.2, and several consequences of these results are discussed in Subsection 2.3.

2.1 Norms and Banach spaces

We fix $T > 0$ and pose

$$\begin{aligned} \|\sigma\|_{H^1(u)}^2 &= \int_0^T \int_{\mathbb{R}^d} |\sigma(t, x)|^2 u(t, dx) dt + \int_0^T \int_{\mathbb{R}^d} (M|\nabla\sigma|(t, x))^2 u(t, dx) dt \\ &= \mathbb{E} \left(\int_0^T |\sigma|^2(t, X_t) dt \right) + \mathbb{E} \left(\int_0^T (M|\nabla\sigma|(t, X_t))^2 dt \right), \end{aligned} \quad (2.1)$$

where M is the usual maximal operator

$$Mf(x) = \sup_r \frac{1}{|B(0, r)|} \int_{B(0, r)} f(x + z) dz.$$

Of course here $|\nabla\sigma|$ and hence $M|\nabla\sigma|$ could have $+\infty$ values on sets of positive Lebesgue measure.

Note that this indeed defines a norm which enjoys the usual properties, semi-continuity for instance, as proved in Section 3.

Proposition 2.1 *The definition (2.1) is a norm. Moreover if $\sigma_n \rightarrow \sigma$ in the sense of distribution then*

$$\|\sigma\|_{H^1(u)} \leq \liminf_n \|\sigma_n\|_{H^1(u)},$$

And if for a given σ , $u_n \geq 0$ converges to u for the weak- topology of measures then*

$$\|\sigma\|_{H^1(u)} \leq \liminf_n \|\sigma\|_{H^1(u_n)}.$$

There are several technical reasons why we use $M|\nabla\sigma|$ in the definition of the norm. Note however that the intuitive definition with just $\nabla\sigma$ would most certainly be too weak as u could for instance vanish just at the points where $\nabla\sigma$ is very large. In particular Prop. 2.1 would not be true.

We also need some similar $W^{1,1}$ assumptions on F . Following the definition of $H^1(u)$, a first attempt would be

$$\|F\|_{W^{1,1}(u)}^2 = \int_0^T \int_{\mathbb{R}^d} M|\nabla F|(t,x) u(t, dx) dt. \quad (2.2)$$

Unfortunately while this definition would work, it is slightly too strong in some cases. This is due to the fact that the maximal operator M is bounded on L^p , $p > 1$, but not on L^1 . In particular if $u \in L^\infty$ then the norm defined in (2.1) would automatically be finite if σ is in the usual H^1 space but the norm defined in (2.2) would *not* be finite if $F \in W^{1,1}$ in general.

Therefore in order to obtain better assumptions we have to work with a more complicated space. Define the modified maximal operator

$$M_L f(x) = \sqrt{\log L} + \int_{B(x,1)} \frac{|f(z)| \mathbb{1}_{|f(z)| \geq \sqrt{\log L}} dz}{(L^{-1} + |x-z|) |x-z|^{d-1}}.$$

Now for any increasing ϕ with $\phi(\xi)/\xi \rightarrow \infty$ as $\phi \rightarrow \infty$, denote

$$\|F\|_{W^{\phi, \text{weak}}(u)} = \sup_{L \geq 1} \frac{\phi(L)}{L \log L} \int_0^T \int_{\mathbb{R}^d} (|F(t,x)| + M_L \nabla F(t,x)) u(t, dx) dt. \quad (2.3)$$

As before, it is easy to show that this defines a well behaved norm

Proposition 2.2 *The definition (2.3) is a norm for any super linear ϕ . Moreover if $F_n \rightarrow F$ in the sense of distribution then*

$$\|F\|_{W^{\phi, \text{weak}}(u)} \leq \liminf_n \|F_n\|_{W^{\phi, \text{weak}}(u)},$$

And if for a given F , $u_n \geq 0$ converges to u for the weak- topology of measures then*

$$\|F\|_{W^{\phi, \text{weak}}(u)} \leq \liminf_n \|F\|_{W^{\phi, \text{weak}}(u_n)}.$$

In the one dimensional case, we can prove strong existence and pathwise uniqueness using $H^{1/2}$ type of assumptions on σ : we define first as usual

$$\partial_x^{1/2}\sigma = \mathcal{F}^{-1}(|\xi|^{1/2} \mathcal{F}\sigma),$$

with \mathcal{F} the Fourier transform in x . Then we pose as before

$$\|\sigma\|_{H^{1/2}(u)}^2 = \int_0^T \int_{\mathbb{R}^d} (M|\partial_x^{1/2}\sigma|(t,x))^2 u(t, dx) dt. \quad (2.4)$$

Again one has

Proposition 2.3 *The definition (2.4) is a norm. Moreover if $\sigma_n \rightarrow \sigma$ in the sense of distribution then*

$$\|\sigma\|_{H^{1/2}(u)} \leq \liminf_n \|\sigma_n\|_{H^{1/2}(u)},$$

And if for a given σ , $u_n \geq 0$ converges to u for the weak-* topology of measures then

$$\|\sigma\|_{H^{1/2}(u)} \leq \liminf_n \|\sigma\|_{H^{1/2}(u_n)}.$$

2.2 General results on strong solutions to (1.1)

In the multi-dimensional case, our most general result is the following one, proved in Section 4.

Theorem 2.4 *One has*

- (i) *Existence: Assume that there exists a sequence of smooth F_n , $\sigma_n \in L^\infty$, such that the solution u_n to (1.4) satisfies for some super linear ϕ , i.e. $\phi(\xi)/\xi \rightarrow \infty$ as $\xi \rightarrow \infty$*

$$\int_0^T \int_{\mathbb{R}^d} (|\sigma_n - \sigma| + |F_n - F|) du_n dt \rightarrow 0, \quad (2.5)$$

$$\sup_n \left(\|F\|_{W^{\phi, weak}(u_n)} + \|\sigma\|_{H^1(u_n)} + \|F_n\|_{L^\infty} + \|\sigma_n\|_{L^\infty} \right) < \infty, \quad (2.6)$$

$$u_n \rightarrow u \text{ for the weak-* topology of measures.} \quad (2.7)$$

Then there exists a strong solution X_t to (1.1) s.t. $(X_t^n - \xi, t \in [0, T])_n$ converges in $L^p(\Omega, L^\infty([0, T]))$ for all $p > 1$ to $(X_t - \xi, t \in [0, T])$, with X_t^n the solutions to (1.3). In addition, $u(dt, dx) = u(t, dx)dt$, where $u(t, \cdot)$ is the law of X_t for all $t \in [0, T]$.

- (ii) *Uniqueness: Let X and Y be two solutions to (1.1) with one-dimensional time marginals $u_X(t, \cdot)$ and $u_Y(t, \cdot)$ on $[0, T]$. Assume that $F \in L^\infty$, $X_0 = Y_0$ a.s. and that*

$$\|F\|_{W^{\phi, \text{weak}}(u_X)} + \|F\|_{W^{\phi, \text{weak}}(u_Y)} + \|\sigma\|_{H^1(u_X)} + \|\sigma\|_{H^1(u_Y)} < \infty$$

for some super linear function ϕ . Then one has pathwise uniqueness: $\sup_{t \in [0, T]} |X_t - Y_t| = 0$ a.s.

Note that we do not require any ellipticity on σ for this result. In that sense we cannot hope to have any smoothing effect from the Wiener process and the assumption on F must be enough to provide well posedness in the purely deterministic setting ($\sigma = 0$). In this case, taking any $u_0 \in L^\infty$, our result gives that there exists a unique solution of $\dot{X}_t = F(t, X_t)$ with $X_0 = \xi$ and with law $u \in L^\infty$ provided that there exists a sequence of regularized F_n s.t. $u_n \rightarrow u$ for the weak-* topology with $u \in L^\infty$ and a super linear ϕ s.t.

$$\sup_{L \geq 1} \frac{\phi(L)}{L \log L} \|F + M_L \nabla F\|_{L^1([0, T] \times \mathbb{R}^d)}.$$

The first point is for example implied by the assumption $\text{div} F \in L^\infty$ and the second one can be proved to hold if $F \in L^1_{t, \text{loc}}(W_x^{1,1})$ as in the proof of Corollary 1.1 below. Hence, we recover the classical results of DiPerna and Lions [5] but not the optimal BV assumption from Ambrosio [2].

In dimension 1, the result is even better: we recover the $H^{1/2}$ type of assumption from [28, 20, 7], but we lose a little bit on F (we have to use (2.2) instead of (2.3)).

Theorem 2.5 *Assume that $d = 1$. One has*

- (i) *Existence: Assume that there exists a sequence of smooth $F_n, \sigma_n \in L^\infty$, such that the solution u_n to (1.4) satisfies*

$$\begin{aligned} & \int_0^T \int_{\mathbb{R}} (|\sigma_n - \sigma| + |F_n - F|) du_n dt \longrightarrow 0, \\ & \sup_n (\|F\|_{W^{1,1}(u_n)} + \|\sigma\|_{H^{1/2}(u_n)} + \|F_n\|_{L^\infty} + \|\sigma_n\|_{L^\infty}) < \infty, \\ & u_n \longrightarrow u \text{ for the weak-* topology of measures.} \end{aligned}$$

Then there exists a strong solution X_t to (1.1) s.t. $(X_t^n - \xi, t \in [0, T])_n$ converges in $L^p(\Omega, L^\infty([0, T]))$ for all $p > 1$ to $(X_t - \xi, t \in [0, T])$, with X_t^n the solutions to (1.3). In addition, $u(dt, dx) = u(t, dx)dt$, where $u(t, \cdot)$ is the law of X_t for all $t \in [0, T]$.

- (ii) *Uniqueness: Let X and Y be two solutions to (1.1) with one-dimensional time marginals $u_X(t, \cdot)$ and $u_Y(t, \cdot)$ on $[0, T]$. Assume that $F \in L^\infty$, $X_0 = Y_0$ a.s. and that*

$$\|F\|_{W^{1,1}(u_X)} + \|F\|_{W^{1,1}(u_Y)} + \|\sigma\|_{H^{1/2}(u_X)} + \|\sigma\|_{H^{1/2}(u_Y)} < \infty.$$

Then pathwise uniqueness holds: $\sup_{t \in [0, T]} |X_t - Y_t| = 0$ a.s.

Of course, while precise, the norms given by (2.1)–(2.3) or (2.4)–(2.2) are not so simple to use. However it is quite easy to deduce more intuitive results with the more usual $W^{1,p}$ norms. We recall that M is continuous onto every L^p space for $1 < p \leq \infty$ and hence appropriate Sobolev norms are controlled by the norms $\|\cdot\|_{H^1(u)}$ and $\|\cdot\|_{W^{1,1}(u)}$ if some L^q estimate is available on the law u .

One complication occurs when $u_X \in L^\infty$ and one wants to obtain the close to optimal $W^{1,1}$ assumption on F (instead of $W^{1,p}$ for some $p > 1$) as the maximal function is not bounded onto L^1 . This is the reason why we defined (2.3), which can be used following [11] (we recall the main steps in the appendix).

Therefore, Theorems 1.1 and 1.2 are simple corollaries of Theorems 2.4 and 2.5, respectively, except for the previous complication for Theorem 1.1.

In order to apply Theorems 1.1 and 1.2, we need to consider cases where it is possible to obtain better integrability than L^1 bounds for a solution to (1.2). This occurs in various situations, some of which will be studied in the next Subsection. One difficulty to apply Theorems 1.1 (ii) and 1.2 (ii) is to obtain pathwise uniqueness without restriction on the set of solutions considered. This will of course be ensured if uniqueness in law is known for (1.1). More precisely, if the conclusion of Theorem 1.1 (i) or Theorem 1.2 (i) holds and there is uniqueness in law for (1.1), then $u_X = u_Y = u$ for all solutions X and Y to (1.1) as in Theorem 1.1 (ii) or Theorem 1.2 (ii) and hence pathwise uniqueness holds. This argument will be used repeatedly in the next subsection.

2.3 Consequences

Let us first consider the case where σ is uniformly elliptic: for all t, x ,

$$\frac{1}{2} \sigma \sigma^*(t, x) = a(t, x) \geq cI \tag{2.8}$$

for some $c > 0$. For example if $F = 0$ and σ does not depend on time, then there exists a corresponding stationary measure $\bar{u} > 0$ in $L^{d/(d-1)}$ as

per Aleksandrov [1]. In that case, when $u_0 \leq C\bar{u}$, then the unique solution u of (1.2) in $L^2_{t,loc}(H^1_x)$ satisfies $u(t, dx) \leq C\bar{u}(x)dx$ for all $t \geq 0$ by the maximum principle.

Corollary 2.6 *Assume that $F = 0$ and $\sigma(x)$ satisfies (2.8) and belongs to $L^\infty \cap W_x^{1,2d}$ (or $L^\infty \cap H^{1/2}$ if $d = 1$). Assume also that $u_0 \leq C\bar{u}$ for some constant $C > 0$. Then one has both existence of a strong solution to (1.1) and pathwise uniqueness.*

Note that pathwise uniqueness holds without additional assumption since $\sigma \in W^{1,2d}$ implies that σ is continuous. And uniqueness in law holds in this case since σ and F are bounded and σ is uniformly elliptic [25, Thm. 7.2.1].

Those results were later extended by Krylov in the parabolic, time dependent case [12, 14]. We may for example use the following version found in [30].

Theorem 2.7 *Assume that F and σ are bounded and σ satisfies (2.8). Then, for all solution X of (1.1) with any initial condition, for all $T > 0$ and $p, q > 1$ such that*

$$\frac{d}{p} + \frac{2}{q} < 2,$$

there exists a constant C such that for all $f \in L^q_t(L^p_x)$

$$\mathbb{E} \left[\int_0^T f(t, X_t) dt \right] \leq C \|f\|_{L^q_t(L^p_x)}.$$

This result means that

$$u \in L^{q'}_t(L^{p'}_x),$$

where $1/p + 1/p' = 1$ and $1/q + 1/q' = 1$, and we obtain the following corollary.

Corollary 2.8 (i) *Assume that $d \geq 2$, $F, \sigma \in L^\infty$, σ satisfies (2.8), $F \in L^{q/2}_{t,loc}(W_x^{1,p/2})$ and $\sigma \in L^q_{t,loc}(W_x^{1,p})$ with $2/q + d/p < 1$. Then one has both existence of a strong solution to (1.1) and pathwise uniqueness for any initial condition ξ .*

(ii) *Assume that $d = 1$, $F, \sigma \in L^\infty$, σ satisfies (2.8), $\sigma \in L^q_{t,loc}(W_x^{1/2,p})$ with $2/q + 1/p < 1$ and $F \in L^{q/2}_{t,loc}(W_x^{1,p/2})$ if $p > 2$, $F \in L^{q/2}_{t,loc}(W^{1,1+\varepsilon})$ for some $\varepsilon > 0$ if $p \leq 2$. Then one has both existence of a strong solution to (1.1) and pathwise uniqueness for any initial condition ξ .*

Note that in this case, pathwise uniqueness holds without additional assumption since Krylov's inequality implies that $u \in L_t^{q'}(L_x^{p'})$ for all solutions to (1.1).

In our setting, since we need additional regularity on σ , it is easy to obtain better a priori estimates for u than those given by Krylov inequality. For instance:

Proposition 2.9 *For any $d \geq 1$, assume $u^0 \in L^1 \cap L^\infty$, $F, \sigma \in L^\infty$, σ satisfies (2.8) and $\nabla\sigma \in L_{t,loc}^q(L_x^p)$ satisfying $2/q + d/p = 1$ with $p > d$. Then any u solution to (1.2), limit of smooth solutions, belongs to $L_t^\infty(L_x^r)$ for any $1 \leq r \leq \infty$.*

This proposition is based on classical energy estimates and hence we just give a very short proof of it in Section 6. Combined with Theorem 1.1 this gives slightly better conditions for σ and much better conditions for F , assuming additional conditions on the initial distribution:

Corollary 2.10 *Assume that $d \geq 2$, $u^0 \in L^1 \cap L^\infty$, $F, \sigma \in L^\infty$, $F \in L_{t,loc}^1(W_x^{1,1})$ and $\nabla\sigma \in L_{t,loc}^q(L_x^p)$, where $2/q + d/p = 1$ with $p > d$. Assume as well that σ satisfies (2.8). Then one has existence of a strong solution to (1.1) with marginal distributions $u(t, dx)$ in $L_{t,loc}^\infty(L_x^\infty)$. In addition, pathwise uniqueness holds among all solutions with marginal distributions in $L_{t,loc}^\infty(L_x^\infty)$.*

As above, the pathwise uniqueness property could be improved if we could prove that uniqueness in law holds. If $d = 2$, uniqueness in law holds when σ and F are bounded and σ is uniformly elliptic [13]. When $d \geq 3$, by Sobolev embedding, the assumption $\nabla\sigma \in L_{t,loc}^q(L_x^p)$ implies that $x \mapsto \sigma(t, x)$ is continuous for almost all $t \geq 0$. This condition is not exactly sufficient to use the result of Stroock and Varadhan [25, Thm. 7.2.1], which assumes that $\sup_{t \in [0, T]} |\sigma(t, x) - \sigma(t, y)| \rightarrow 0$ when $y \rightarrow x$. This is true for example if $\nabla\sigma \in L_{t,loc}^\infty(L_x^p)$ for $p > d$.

Hence we obtain for (1.1)

Corollary 2.11 *Assume that $d \geq 2$, $u^0 \in L^1 \cap L^\infty$, $F, \sigma \in L^\infty$, $F \in L_{t,loc}^1(W_x^{1,1})$ and $\nabla\sigma \in L_{t,loc}^q(L_x^p)$ where $2/q + d/p = 1$ with $p > d$. Assume as well that σ satisfies (2.8), and if $d \geq 3$ that for all x ,*

$$\sup_{t \in [0, T]} |\sigma(t, x) - \sigma(t, y)| \rightarrow 0 \quad \text{when } y \rightarrow x.$$

Then one has both existence of a strong solution to (1.1) and pathwise uniqueness.

This result can be compared with previous works dealing with the uniformly elliptic case. The best results in this case seem to be those of [30] and [21]. In the first work, strong existence and pathwise uniqueness are proved under the assumptions $\nabla\sigma \in L_{t,loc}^q(L_x^p)$, $\sigma(t, x)$ uniformly continuous with respect to x and $F \in L_{t,loc}^q(L_x^p)$ with $d/p + 2/q < 1$, so we obtain a slightly better condition on σ (we can handle the limit case $d/p + 2/q = 1$ and no uniform continuity is needed for strong existence), and a condition on F which is neither stronger nor weaker, since $L_{t,loc}^1(W_x^{1,1})$ neither contains nor is contained in $L_{t,loc}^q(L_x^p)$ with $d/p + 2/q < 1$. In the second work, since the approach for pathwise uniqueness is very different, the conditions obtained are of a different nature as ours. In particular, this work requires additional boundedness assumptions on $\text{div } \sigma$ and $(D\sigma)^2$.

In dimension 1 in the stationary case, even if (2.8) is not satisfied but instead only

$$\frac{1}{2}\sigma^2(x) = a(x) > 0, \quad (2.9)$$

then one has the a priori bound

$$u(t, x) \leq \frac{C}{a(x)} e^{\int_0^x \frac{F(y)}{a(y)} dy},$$

for solutions to (1.2) again provided that u^0 satisfies the same bound. Therefore, we obtain

Corollary 2.12 *Assume $d = 1$, $\sigma, F \in L^\infty$, σ satisfies (2.9), $F/a \in L^1$,*

$$u_0(x) \leq \frac{C}{a(x)} e^{\int_0^x \frac{F(y)}{a(y)} dy}$$

and

$$\int_{\mathbb{R}} \frac{(M|\partial_x^{1/2}\sigma|(x))^2}{a(x)} dx < \infty \quad \text{and} \quad \int_{\mathbb{R}} \frac{M|\nabla F|}{a(x)} dx < \infty. \quad (2.10)$$

Then one has both existence of a strong solution to (1.1) and pathwise uniqueness.

Note that the assumptions (2.10) imply that $a^{-1} \in L_{loc}^1$, which is a necessary and sufficient condition for uniqueness in law when F is bounded [7].

We will prove in Lemma 3.3 of Section 3 that for all x, y

$$|\sigma(x) - \sigma(y)| \leq \left(M|\partial_x^{1/2}\sigma|(x) + M|\partial_x^{1/2}\sigma|(y) \right) |x - y|^{1/2}. \quad (2.11)$$

This inequality allows us to compare our result with similar results of the literature [28, 31, 20, 7]. The best conditions in the time homogeneous case seem to be those of [7, Thm. 5.53] and [28]. The first work assumes that $|\sigma(x) - \sigma(y)| \leq C\sqrt{|x - y|}$ and that $F/a \in L^1_{loc}$, so our result gives better conditions for σ , but worse conditions on F . The second work considers the time-inhomogeneous case and assumes that $F(t, x)$ is uniformly Lipschitz in the variable x and $|\sigma(t, x) - \sigma(t, y)| \leq h(|x - y|)$ where the function h is strictly increasing and satisfies $\int_{0+} \rho^{-2}(u)du = +\infty$. Our conditions on F are better, our conditions on σ do not directly compare with the last ones. However a typical scale for h is $h(u) = \sqrt{u}$ and in that case, by (2.11), our bound on $|\sigma(x) - \sigma(y)|$ is less stringent. We can also compare with known results in the case where $F = 0$. The best result in this case seems to be the one of [7], which assumes that there exist a function f on \mathbb{R} and a strictly increasing function h on \mathbb{R}_+ such that $|\sigma(y) - \sigma(x)| \leq f(x)h(|y - x|)$ for all x, y , $f/a \in L^1_{loc}$ and $\int_{0+} \rho^{-2}(u)du = +\infty$. Our result is slightly weaker than this one since we must take $h(u) = \sqrt{u}$ as above, but the bound (2.11) is more general than the one of [7].

We point out that, in higher dimension as well, ellipticity is not always required for bounds on the law. We give the classical example of SDE's in the phase space \mathbb{R}^{2d}

$$dX_t = V_t, \quad dV_t = F(t, X_t)dt + \sigma(t, X_t) dW_t, \quad X_0 = x, \quad V_0 = v. \quad (2.12)$$

The law $u(t, x, v)$ of the joint process $(X_t, V_t)_{t \geq 0}$ solves the kinetic equation

$$\partial_t u(t, x, v) + v \cdot \nabla_x u(t, x, v) + F(t, x) \cdot \nabla_v u(t, x, v) = \sum_{1 \leq i, j \leq d} a_{ij}(t, x) \frac{\partial^2 u(t, x, v)}{\partial v_i \partial v_j}. \quad (2.13)$$

Eq. (2.13) is in fact better behaved than (1.2) for rough coefficients as its symplectic structure for instance guarantees that it satisfies a maximum principle for all measure-valued solutions: note that the rough coefficients are only in t, x and always multiply derivatives in v . In particular there is uniqueness among all measure-valued solutions, and if $u^0 \in L^\infty(\mathbb{R}^{2d})$ then $u \in L^\infty(\mathbb{R}_+ \times \mathbb{R}^{2d})$. This is true even though the diffusion in (2.12) is degenerate (there is no diffusion in the x direction, and σ can also be degenerate).

Hence in this situation, one obtains an even better result.

Corollary 2.13 *Assume that $\sigma \in L^\infty \cap L^2_{t,loc}(H^1_x)$ and $F \in L^1_{t,loc}(W_x^{1,1})$. Assume also that $u_0 \in L^\infty$. Then one has both existence of a strong solution to (2.12) and pathwise uniqueness.*

To conclude, let us observe that most of the previous results give strong existence for smooth (and so non deterministic) initial distributions. However, one can use the next result to obtain strong existence and pathwise uniqueness for almost all deterministic initial conditions.

Proposition 2.14 *Under the assumptions of either Corollary 2.6, Corollary 2.11, Corollary 2.12 or Corollary 2.13, for any complete filtered probability space $(\Omega, (\mathcal{F}_t)_{t \geq 0}, \mathbb{P})$ equipped with a r -dimensional standard Brownian motion W , there is strong existence and pathwise uniqueness for (1.1) on $(\Omega, (\mathcal{F}_t)_{t \geq 0}, \mathbb{P}, W)$ for almost all deterministic initial condition $\xi = x \in \mathbb{R}^d$.*

The proofs of the previous results are organized as follows. We start in Section 3 with some simple technical proofs, including those of Propositions 2.1, 2.2 and 2.3, Section 4 is then devoted to the proof of Theorem 2.4, Section 5 to the proof of Theorem 2.5, Section 6 to the proof of Proposition 2.9, and Section 7 to the proof of Proposition 2.14. The proof of Theorem 1.1 is given in Appendix 7.

3 Useful technical results

The results and proofs presented in this section are mostly easy extensions of well-known techniques, which we need in following sections and hence include here for the sake of completeness.

3.1 Pointwise difference estimates

We often need to estimate the difference of the coefficients σ of F at two different points x and y during the proofs. Hence we collect here all the results which allow us to do so and that we later use. In all those estimates, time is only a parameter and we accordingly omit the time variable in most formulas.

We start by recalling the classical inequality (see [24] for instance)

$$|\sigma(t, x) - \sigma(t, y)| \leq (M|\nabla_x \sigma|(t, x) + M|\nabla_x \sigma|(t, y)) |x - y|. \quad (3.1)$$

We next turn to an extension with the operator M_L used in the definition (2.3)

Lemma 3.1 *Assume that F is measurable and $|\nabla F|$ is a measure then for any $x, y \in \mathbb{R}^d$*

$$|F(t, x) - F(t, y)| \leq (h(t, x) + h(t, y)) \left(|x - y| + \frac{1}{L} \right),$$

with $h(t, x) = |F(t, x)| + M_L \nabla F(t, x)$.

Proof First observe that by the definition of h , the result is obvious if $|x - y| \leq 1/L$ or if $|x - y| \geq 1$. Assume now that $1/L \leq |x - y| \leq 1$. We recall the Lemma from [11]

Lemma 3.2 *Assume F is measurable and $|\nabla F|$ is a measure. There exists a constant C s.t. for any x, y*

$$|F(x) - F(y)| \leq C \int_{B(x,y)} |\nabla F(z)| \left(\frac{1}{|x - z|^{d-1}} + \frac{1}{|y - z|^{d-1}} \right) dz, \quad (3.2)$$

where $B(x, y)$ denotes the ball of center $(x + y)/2$ and diameter $|x - y|$.

Now $|\nabla F| \leq \sqrt{\log L} + |\nabla F| \mathbb{I}_{|\nabla F| \geq \sqrt{\log L}}$ and thus

$$\frac{1}{|x - y|} \int_{B(x,y)} \frac{|\nabla F(z)|}{|x - z|^{d-1}} dz \leq C \sqrt{\log L} + \int_{B(x,1)} \frac{|\nabla F(z)| \mathbb{I}_{|\nabla F| \geq \sqrt{\log L}}}{(1/L + |x - z|) |x - z|^{d-1}},$$

where we used that if $z \in B(x, y)$ then $|x - z| + 1/L \leq 2|x - y|$. By the definition of M_L , this concludes the proof. \square

Let us turn now to our last bound which uses $\partial_x^{1/2} \sigma$

Lemma 3.3 *Assume that σ and $\partial_x^{1/2} \sigma$ are measurable then for any x, y*

$$|\sigma(t, x) - \sigma(t, y)| \leq \left(M |\partial_x^{1/2} \sigma|(t, x) + M |\partial_x^{1/2} \sigma|(t, y) \right) |x - y|^{1/2}.$$

Proof By the definition of $\partial_x^{1/2} \sigma$

$$\sigma(x) = K \star \partial_x^{1/2} \sigma,$$

for the convolution kernel K with $\hat{K} = |\xi|^{-1/2}$, which implies that

$$|K(x)| \leq C |x|^{d-1/2}, \quad |\nabla K(x)| \leq C |x|^{d+1/2}. \quad (3.3)$$

Now simply compute

$$\begin{aligned} |\sigma(x) - \sigma(y)| &\leq \int_{|z-x| \geq 2|x-y|} |K(x-z) - K(y-z)| |\partial_x^{1/2} \sigma(z)| dz \\ &\quad + \int_{|z-x| \leq 2|x-y|} (|K(x-z)| + |K(y-z)|) |\partial_x^{1/2} \sigma(z)| dz. \end{aligned}$$

Denote $|x-y| = r$. One has by (3.3)

$$\begin{aligned} \int_{|z-x| \leq 2r} |K(x-z)| |\partial_x^{1/2} \sigma(z)| dz &\leq \sum_{n \geq -1} \int_{|z-x| \leq 2^{-n} r} \frac{2^{n(d-1/2)}}{r^{d-1/2}} |\partial_x^{1/2} \sigma(z)| dz \\ &\leq \sum_{n \geq -1} 2^{-n/2} r^{1/2} M |\partial_x^{1/2} \sigma|(x) = C r^{1/2} M |\partial_x^{1/2} \sigma|(x). \end{aligned}$$

Since $|z-x| \leq 2r$ implies that $|z-y| \leq 3r$, one has the same inequality

$$\int_{|z-x| \leq 2r} |K(y-z)| |\partial_x^{1/2} \sigma(z)| dz \leq C r^{1/2} M |\partial_x^{1/2} \sigma|(y).$$

As for the last term, first note that if $|x-z| \geq 2|x-y|$ then $|y-z| \geq |x-z|/2$. Hence by (3.3) if $|x-z| \geq 2|x-y|$

$$|K(x-z) - K(y-z)| \leq C \frac{|x-y|}{|x-z|^{d+1/2}}.$$

Therefore

$$\begin{aligned} &\int_{|z-x| \geq 2|x-y|} |K(x-z) - K(y-z)| |\partial_x^{1/2} \sigma(z)| dz \\ &\leq \sum_{n \geq 1} \int_{|z-x| \geq 2^n r} C \frac{r}{(2^n r)^{d+1/2}} |\partial_x^{1/2} \sigma(z)| dz \\ &\leq C r^{1/2} \sum_{n \geq 1} 2^{-n/2} M |\partial_x^{1/2} \sigma|(x) \leq C r^{1/2} M |\partial_x^{1/2} \sigma|(x). \end{aligned}$$

Summing up the three estimates concludes the proof. \square

3.2 Proof of Prop. 2.1, 2.2, 2.3

Note that the time variable again plays essentially no role here. We may of course assume that u is not identically 0.

Let us first check that $\|\cdot\|_{H^1(u)}$ is a norm. The triangle inequality and the equality $\|\lambda\sigma\|_{H^1(u)} = |\lambda| \|\sigma\|_{H^1(u)}$ are straightforward. Now assume that $\|\sigma\|_{H^1(u)} = 0$.

This means that $\sigma = 0$ and $M|\nabla\sigma| = 0$ on the support of u . Since this support contains at least one point and by the definition of the maximal operator, $\nabla\sigma$ is identically 0. Thus σ is a constant which is necessarily 0 as it has to vanish on the support of u .

Now let $\sigma_n \rightarrow \sigma$ in the sense of distributions. Take any point x and any $c > 1$

$$\begin{aligned} \frac{1}{|B(0,r)|} \int_{B(0,r)} |\nabla\sigma|(x+z) dz &\leq \frac{1}{|B(0,r)|} \liminf \int_{B(0,cr)} |\nabla\sigma_n|(x+z) dz \\ &\leq c^d \liminf M|\nabla\sigma_n|(x). \end{aligned}$$

Taking now the supremum in r , we deduce that for any $c > 1$

$$M|\nabla\sigma|(x) \leq c^d \liminf M|\nabla\sigma_n|(x).$$

Apply now Fatou's lemma and let c go to 1 to deduce

$$\int (M|\nabla\sigma|(x))^2 u(dx) \leq \liminf \int (M|\nabla\sigma_n|(x))^2 u(dx).$$

Using (3.1), it is easy to deduce the same inequality on the full $H^1(u)$ norm.

Let us now turn to the last part. Denote $f = |\nabla\sigma|$, f is a non negative, measurable function, possibly with $+\infty$ values on large sets. Then $g = (Mf)^2$ is non negative, measurable, lower semi-continuous and again possibly with $+\infty$ values on large sets, see [24] for instance. Note that for any positive measure μ

$$\int g d\mu = \int_0^\infty \int \mathbb{I}_{g(x) > \xi} \mu(dx) d\xi.$$

Now assume $u_n \rightarrow u$ in the weak-* topology of M^1 with $u_n \geq 0$. Note that for any open set O

$$\int_O du \leq \liminf \int_O du_n.$$

Take $O = \{g(x) > \xi\}$ which is open by the lower semi-continuity of g . Therefore

$$\int g du \leq \liminf \int g du_n,$$

which finishes the proof of Prop. 2.1.

Prop. 2.2 and 2.3 are proved in exactly the same manner.

4 Proof of Theorem 2.4

We use two types of estimates; one is based on an explicit quantitative estimate which generalizes the one in [4] for Ordinary Differential Equations and one which generalizes the local time which is used in dimension 1 in the classical approach [28, 20, 7]. We use the first quantitative estimate to prove existence and the second one to prove uniqueness (though with suitable modifications any one could be used for both existence and uniqueness).

The first method is more precise but slightly more complicated than the second.

4.1 Existence

We consider the sequence of solutions to the regularized problem (1.3), and assume it satisfies the assumptions of Th. 2.4. We fix $T > 0$ in all the proof. The proof is based on estimates on the expectation of the family of quantities

$$Q_{nm}^{(\varepsilon)}(t) = \log \left(1 + \frac{|X_t^n - X_t^m|^2}{\varepsilon^2} \right), \quad (4.1)$$

given in the following lemma.

Lemma 4.1 *There exists a constant C such that, for all $0 < \varepsilon \leq 1$ and $n, m \geq 1$,*

$$\sup_{t \in [0, T]} \mathbb{E}(Q_{nm}^{(\varepsilon)}(t)) \leq C (1 + |\log \varepsilon| \tilde{\eta}(\varepsilon)) + C \frac{\eta(n, m)}{\varepsilon^2}, \quad (4.2)$$

where $\eta(n, m) \rightarrow 0$ when $n, m \rightarrow +\infty$ and $\tilde{\eta}(\varepsilon) := (\varepsilon \phi(\varepsilon^{-1}))^{-1} \rightarrow 0$ when $\varepsilon \rightarrow 0$.

Proof Note that

$$|\nabla(\log(1 + |x|^2/\varepsilon))| = \left| \frac{2x}{\varepsilon^2 + |x|^2} \right| \leq \frac{C}{\varepsilon + |x|}$$

and

$$|\nabla^2(\log(1 + |x|^2/\varepsilon))| = \left| \nabla \left(\frac{2x}{\varepsilon^2 + |x|^2} \right) \right| \leq \frac{C}{\varepsilon^2 + |x|^2}.$$

Thus, by Itô's formula and since $\sup_n(\|\sigma_n\|_\infty + \|F_n\|_\infty) < +\infty$, for any C_b^2 function f ,

$$\begin{aligned}
\mathbb{E}(f(X_t^n - X_t^m)) &= f(0) + \frac{1}{2} \int_0^t \mathbb{E}(\nabla^2 f(X_s^n - X_s^m) (\sigma_n \sigma_n^*(X_s^n) \\
&\quad + \sigma_m \sigma_m^*(X_s^m) - \sigma_n(X_s^n) \sigma_m(X_s^m) - \sigma_m(X_s^m) \sigma_n^*(X_s^n)) ds \\
&\quad + \int_0^t \mathbb{E}(\nabla f(X_s^n - X_s^m) \cdot (F(s, X_s^n) - F(s, X_s^m))) ds \\
&\leq f(0) + \frac{1}{2} \int_0^t \mathbb{E}(|\nabla^2 f(X_s^n - X_s^m)| (|\sigma(X_s^n) - \sigma(X_s^m)|^2 \\
&\quad + \sup_k \|\sigma_k\|_{L^\infty} (|\sigma_n(X_s^n) - \sigma(X_s^n)| + |\sigma_m(X_s^m) - \sigma(X_s^m)|))) ds \\
&\quad + \int_0^t \mathbb{E}(|\nabla f(X_s^n - X_s^m)| |F_n(s, X_s^n) - F_m(s, X_s^m)|) ds.
\end{aligned} \tag{4.3}$$

Hence

$$\begin{aligned}
\mathbb{E}(Q_{nm}^{(\varepsilon)}(t)) &\leq C \int_0^t \mathbb{E} \left(\frac{|\sigma(s, X_s^n) - \sigma(s, X_s^m)|^2}{\varepsilon^2 + |X_s^n - X_s^m|^2} \right) ds + C \frac{\eta(n, m)}{\varepsilon^2} \\
&\quad + C \int_0^t \mathbb{E} \left(\frac{|F(s, X_s^n) - F(s, X_s^m)|}{\varepsilon + |X_s^n - X_s^m|} \right) ds,
\end{aligned} \tag{4.4}$$

with C a constant independent of n and ε and $\eta(n, m) \rightarrow 0$ as $n, m \rightarrow \infty$ by Assumptions (2.5) and (2.6).

Now as $\|\sigma\|_{H^1(u_n)} + \|\sigma\|_{H^1(u_m)} < \infty$, denoting $h = M|\nabla\sigma|$,

$$\int_0^T \int h^2(t, x) (u_n(t, dx) + u_m(t, dx)) dt \leq \|\sigma\|_{H^1(u_n)} + \|\sigma\|_{H^1(u_m)} \leq C,$$

with C independent of n, m and ε . Now,

$$\int_0^t \mathbb{E} \left(\frac{|\sigma(s, X_s^n) - \sigma(s, X_s^m)|^2}{\varepsilon^2 + |X_s^n - X_s^m|^2} \right) ds \leq \int_0^t \mathbb{E}(h^2(s, X_s^n) + h^2(s, X_s^m)) ds.$$

As u_n is the law of X_s^n then one obtains that

$$\int_0^t \mathbb{E} \left(\frac{|\sigma(s, X_s^n) - \sigma(s, X_s^m)|^2}{\varepsilon^2 + |X_s^n - X_s^m|^2} \right) ds \leq C.$$

We now turn to the term involving F and introduce the corresponding $h = |F| + M_{1/\varepsilon} \nabla F$.

By Lemma 3.1

$$\begin{aligned} & \int_0^t \mathbb{E} \left(\frac{|F(s, X_n^s) - F(s, X_m^s)|}{\varepsilon + |X_n^s - X_m^s|} \right) ds \\ & \leq \int_0^t \int h(s, x) (u_n(s, x) + u_m(s, x)) dx ds \end{aligned}$$

By the definition (2.3)

$$\int_0^t \int h(s, x) (u_n(s, x) + u_m(s, x)) dx ds \leq C \frac{|\log \varepsilon|}{\varepsilon \phi(\varepsilon^{-1})}.$$

Define $\tilde{\eta}(\varepsilon) = (\varepsilon \phi(\varepsilon^{-1}))^{-1} \rightarrow 0$ as $\varepsilon \rightarrow 0$ since ϕ is super linear.

Combining the previous inequalities, we obtain (4.2). \square

Fix $p > 1$. The next step consists in deducing from Lemma 4.1 that $(X_t^n - \xi)$ is a Cauchy sequence in $L^p(\Omega, L^\infty([0, T]))$. Since F_n and σ_n are uniformly bounded, it is standard to prove that $X_t^n - \xi \in L^p(\Omega, L^\infty([0, T]))$ for all $n \geq 1$, so we only need to prove the next lemma.

Lemma 4.2 For all $p > 1$,

$$\mathbb{E} \left(\sup_{t \in [0, T]} |X_t^n - X_t^m|^p \right) \rightarrow 0 \quad \text{as } n, m \rightarrow +\infty. \quad (4.5)$$

Proof For fixed t , for any ε and L s.t. $0 < \varepsilon < L$,

$$\begin{aligned} \mathbb{E}(|X_t^n - X_t^m|^p) & \leq \mathbb{E}(|X_t^n - X_t^m|^p; |X_t^n - X_t^m| \geq L) + \varepsilon^{p/2} \\ & \quad + L^p \mathbb{P}(|X_t^n - X_t^m| \geq \sqrt{\varepsilon}). \end{aligned}$$

Note that

$$\mathbb{E}(|X_t^n - X_t^m|^p; |X_t^n - X_t^m| \geq L) \leq \frac{1}{L} (\mathbb{E}(|X_t^n - \xi|^{p+1}) + \mathbb{E}(|X_t^m - \xi|^{p+1})).$$

By the inequality of Burkholder-Davis-Gundy and since F_n and σ_n are uniformly bounded, it is standard to check that

$$\sup_{n \geq 1, t \in [0, T]} \mathbb{E}(|X_t^n - \xi|^{p+1}) < +\infty.$$

Finally

$$\mathbb{P}(|X_t^n - X_t^m| \geq \sqrt{\varepsilon}) \leq \frac{\mathbb{E}Q_{nm}^{(\varepsilon)}(t)}{|\log \varepsilon|}.$$

Thus

$$\mathbb{E}(|X_t^n - X_t^m|^p) \leq C \left[\frac{1}{L} + \varepsilon^{p/2} + \frac{L^p}{|\log \varepsilon|} \left(1 + |\log \varepsilon| \tilde{\eta}(\varepsilon) + \frac{\eta(n, m)}{\varepsilon^2} \right) \right].$$

Taking for example $\varepsilon^2 = \eta(n, m)$ and $L = \left(\frac{1}{|\log \varepsilon|} + \tilde{\eta}(\varepsilon) \right)^{-1/2p}$, one concludes that

$$\sup_{t \in [0, T]} \mathbb{E}(|X_t^n - X_t^m|^p) \rightarrow 0 \quad \text{as } n, m \rightarrow +\infty$$

holds.

In order to pass the supremum inside the expectation, it suffices to observe that the computation of (4.3–4.4) in the proof of Lemma 4.1 can be applied to $|A_{t \wedge \tau}^n - A_{t \wedge \tau}^m|^2 \vee |M_{t \wedge \tau}^n - M_{t \wedge \tau}^m|^2$, where τ is any stopping time and $X_t^n = \xi + A_t^n + M_t^n$ is Doob's decomposition of the semi martingale X_t^n , i.e.

$$A_t^n = \int_0^t F(s, X_s^n) ds \quad \text{and} \quad M_t^n = \int_0^t \sigma(s, X_s^n) dW_t.$$

Note that to be fully rigorous, one first needs to regularize the supremum \vee .

Instead of (4.4), we obtain

$$\begin{aligned} & \mathbb{E} \log \left(1 + \frac{|A_{t \wedge \tau}^n - A_{t \wedge \tau}^m|^2 \vee |M_{t \wedge \tau}^n - M_{t \wedge \tau}^m|^2}{\varepsilon^2} \right) \\ & \leq C \int_0^t \mathbb{E} \left(\frac{|\sigma(s, X_s^n) - \sigma(s, X_s^m)|^2}{\varepsilon^2 + |A_t^n - A_t^m|^2 \vee |M_t^n - M_t^m|^2} \right) ds + C \frac{\eta(n, m)}{\varepsilon^2} \\ & \quad + C \int_0^t \mathbb{E} \left(\frac{|F(s, X_s^n) - F(s, X_s^m)|}{\varepsilon + |A_t^n - A_t^m| \vee |M_t^n - M_t^m|} \right) ds, \end{aligned}$$

or

$$\begin{aligned} & \mathbb{E} \log \left(1 + \frac{|A_{t \wedge \tau}^n - A_{t \wedge \tau}^m|^2 \vee |M_{t \wedge \tau}^n - M_{t \wedge \tau}^m|^2}{\varepsilon^2} \right) \\ & \leq C \int_0^t \mathbb{E} \left(\frac{|\sigma(s, X_s^n) - \sigma(s, X_s^m)|^2}{\varepsilon^2 + \frac{1}{4}|X_s^n - X_s^m|^2} \right) ds + C \frac{\eta(n, m)}{\varepsilon^2} \\ & \quad + C \int_0^t \mathbb{E} \left(\frac{|F(s, X_s^n) - F(s, X_s^m)|}{\varepsilon + \frac{1}{2}|X_t^n - X_t^m|} \right) ds. \end{aligned}$$

Therefore, the same computation as in Lemma 4.1 gives

$$\sup_{t \in [0, T], \tau \text{ stopping time}} \mathbb{E}(|A_{t \wedge \tau}^n - A_{t \wedge \tau}^m|^p \vee |M_{t \wedge \tau}^n - M_{t \wedge \tau}^m|^p) \rightarrow 0 \quad \text{as } n, m \rightarrow +\infty.$$

Since $p > 1$, Doob's inequality entails

$$\mathbb{E}(\sup_{t \in [0, T]} |M_t^n - M_t^m|^p) \rightarrow 0 \quad \text{as } n, m \rightarrow +\infty.$$

Fix $\eta > 0$, and fix n_0 such that

$$\sup_{t \in [0, T], \tau \text{ stopping time}} \mathbb{E}(|A_{t \wedge \tau}^n - A_{t \wedge \tau}^m|^p) \leq \eta$$

for all $n, m \geq n_0$. For all $M > 0$, let $\tau = \inf\{t \geq 0 : |A_t^n - A_t^m| \geq M\}$. Then

$$\mathbb{P}(\sup_{t \in [0, T]} |A_t^n - A_t^m| \geq M) = \mathbb{P}(\tau \leq T) \leq \frac{\eta}{M^p}.$$

Now, for all $1 < q < p$,

$$\begin{aligned} \mathbb{E}(\sup_{t \in [0, T]} |A_t^n - A_t^m|^q) &= q \int_0^{+\infty} x^{q-1} \mathbb{P}(\sup_{t \in [0, T]} |A_t^n - A_t^m| \geq x) dx \\ &\leq q \int_0^{+\infty} x^{q-1} \left(\frac{\eta}{x^p} \wedge 1 \right) dx = \frac{p \eta^{q/p}}{p - q}. \end{aligned}$$

Therefore

$$\mathbb{E}(\sup_{t \in [0, T]} |A_t^n - A_t^m|^q) \rightarrow 0 \quad \text{as } n, m \rightarrow +\infty,$$

which concludes the proof of (4.5). \square

From the fact that $(X^n - \xi)$ is a Cauchy sequence in $L^p(\Omega, L^\infty([0, T]))$, it is standard to deduce the almost sure convergence for the L^∞ norm of a subsequence of $(X_t^n, t \in [0, T])_n$ to a process $(X_t, t \in [0, T])$ such that $(X_t - \xi, t \in [0, T]) \in L^p(\Omega, L^\infty([0, T]))$ for all $p > 1$. Since the convergence holds for the L^∞ norm, the process X is a.s. continuous and adapted to the filtration $(\mathcal{F}_t)_{t \geq 0}$.

Since u_n converges to u in the weak-* topology of measures, we have for all bounded continuous function f on $[0, T] \times \mathbb{R}^d$

$$\mathbb{E} \int_0^T f(t, X_t) dt = \int_{\mathbb{R}^d} \int_0^T f(t, x) u(dt, dx).$$

so $u(dt, dx) = u(t, dx)dt$, where $u(t, dx)$ is the law of X_t .

Defining for all $t \in [0, T]$

$$Y_t := \int_0^t F(s, X_s) ds + \int_0^t \sigma(s, X_s) dW_s,$$

it only remains to check that $Y_t = X_t$ for all $t \in [0, T]$, a.s., i.e. by continuity that $Y_t = X_t$ a.s., for all $t \in [0, T]$.

As

$$X_t^n = \int_0^t F_n(s, X_s^n) ds + \int_0^t \sigma_n(s, X_s^n) dW_s,$$

one has $Y_t = X_t$ provided that

$$\int_0^t \mathbb{E}(|F_n(s, X_s^n) - F(s, X_s)| + |\sigma_n(s, X_s^n) - \sigma(s, X_s)|^2) ds \longrightarrow 0.$$

From the assumption (2.5) and the L^∞ bounds on F and σ (2.6), this is implied by: For any fixed ε

$$\int_0^T \mathbb{P}(|F(s, X_s^n) - F(s, X_s)| > \varepsilon) + \mathbb{P}(|\sigma(s, X_s^n) - \sigma(s, X_s)| > \varepsilon) ds \longrightarrow 0.$$

By the almost sure convergence of X_s^n this would be automatic if F and σ are continuous or if the law u_n was absolutely continuous with respect to the Lebesgue measure and equi-integrable (using then the Lebesgue points of F and σ). In general however we require some additional work. We prove it for σ , the argument for F being fully similar.

By Prop. 2.1

$$\begin{aligned} & \int_0^T \int_{\mathbb{R}^d} (M|\nabla\sigma(t, x)|)^2 (u(t, dx) + u_n(t, dx)) dt \\ & \leq \|\sigma\|_{H^1(u_n)} + \liminf \|\sigma\|_{H^1(u_n)} \leq C. \end{aligned}$$

Now by (3.1)

$$\begin{aligned} & \mathbb{P}(|\sigma(s, X_s^n) - \sigma(s, X_s)| > \varepsilon) \\ & \leq \mathbb{P}((M|\nabla\sigma|(s, X_s^n) + M|\nabla\sigma|(s, X_s)) > \varepsilon/|X_s^n - X_s|) \\ & \leq \mathbb{P}(|X_s^n - X_s| > \varepsilon^2) + \mathbb{P}(M|\nabla\sigma|(s, X_s^n) \geq \frac{1}{2\varepsilon}) + \mathbb{P}(M|\nabla\sigma|(s, X_s) \geq \frac{1}{2\varepsilon}), \end{aligned}$$

and one easily concludes as $|X_s^n - X_s| \longrightarrow 0$ almost surely.

Note that this shows that for this precise point, $\|\sigma\|_{H^s(u)} < \infty$ for some $s \in (0, 1)$ would be enough instead of $\|\sigma\|_{H^1(u)} < \infty$.

4.2 Uniqueness

Consider two solutions X and Y satisfying the assumptions of point (ii) in Th. 2.4. Define a family of functions $(L_\varepsilon)_\varepsilon$ in $C^\infty(\mathbb{R}^d)$ satisfying

$$L_\varepsilon(x) = 1 \text{ if } |x| \geq \varepsilon, \quad L_\varepsilon(x) = 0 \text{ if } |x| \leq \varepsilon/2, \quad \varepsilon \|\nabla L_\varepsilon\|_{L^\infty} + \varepsilon^2 \|\nabla^2 L_\varepsilon\| \leq C,$$

with C independent of ε , and $L_\varepsilon(x) \geq L_{\varepsilon'}(x)$ for all $\varepsilon \leq \varepsilon'$ and $x \in \mathbb{R}^d$. Use Itô's formula

$$\begin{aligned} \mathbb{E}(L_\varepsilon(X_t - Y_t)) &= L(0) + \int_0^t \mathbb{E}(\nabla L_\varepsilon(X_s - Y_s) \cdot (F(s, X_s) - F(s, Y_s))) ds \\ &\quad + \int_0^t \mathbb{E}\left(\nabla^2 L_\varepsilon(X_s - Y_s) : (\sigma\sigma^*(X_s) \right. \\ &\quad \left. + \sigma\sigma^*(Y_s) - \sigma(X_s)\sigma^*(Y_s) - \sigma(Y_s)\sigma^*(X_s))\right) ds. \end{aligned}$$

Hence

$$\begin{aligned} \mathbb{E}(L_\varepsilon(X_t - Y_t)) &\leq C \int_0^t \mathbb{E}\left(\mathbb{1}_{\varepsilon/2 \leq |X_t - Y_t| \leq \varepsilon} \left(\frac{|\sigma(s, X_s) - \sigma(s, Y_s)|^2}{\varepsilon^2} \right. \right. \\ &\quad \left. \left. + \frac{|F(s, X_s) - F(s, Y_s)|}{\varepsilon} \right)\right) ds. \end{aligned}$$

Now denote $h = M|\nabla\sigma|$ so that

$$\int_0^T \int |h(t, x)|^2 (u_X(t, dx) + u_Y(t, dx)) dt \leq C < \infty.$$

Define as well $\tilde{h}_\varepsilon = |F| + M_{1/\varepsilon}\nabla F$ s.t.

$$\int_0^T \int \tilde{h}_\varepsilon (u_X + u_Y) dx ds \leq \frac{C |\log \varepsilon|}{\varepsilon \phi(\varepsilon^{-1})}.$$

The corresponding computation involving \tilde{h}_ε is now tricky, precisely because of the dependence on ε in \tilde{h}_ε . To simplify it, we will use a slightly different definition.

First note that one can always replace ϕ by a function growing slower (as long as it is still super linear). Without loss of generality, we may hence assume that $\phi(\xi)/\xi$ is a non-decreasing function which grows at most like $\log \xi$ and in particular that

$$\frac{1}{C} \varepsilon \phi(\varepsilon^{-1}) \leq \frac{\phi(\xi)}{\xi} \leq C \varepsilon \phi(\varepsilon^{-1}) \quad \forall \xi \in [\varepsilon^{-1/2}, \varepsilon^{-1}].$$

Consider a partition of $(0, 1)$ in $\bigcup_i I_i$ where the $I_i = [a_i, b_i)$ are disjoint with $b_i = \sqrt{a_i}$ (except for $I_0 := [1/2, 1)$) so that

$$|I_i| \sim \sqrt{a_i} \quad \text{when } i \rightarrow +\infty.$$

Now for any $\varepsilon \in I_i$, choose $\bar{h}_\varepsilon = \tilde{h}_{a_i}$. One has

$$\int_0^T \int \bar{h}_\varepsilon(t, x) (u_X(t, x) + u_Y(t, x)) dx dt \leq C \frac{|\log \varepsilon|}{\varepsilon \phi(\varepsilon)} \leq 2C^2 \frac{|\log b_i|}{b_i \phi(b_i^{-1})}.$$

Now by (3.1) and Lemma 3.1

$$\begin{aligned} \mathbb{E}(L_\varepsilon(X_t - Y_t)) &\leq C \int_0^t \mathbb{E} [(h^2(s, X_s) + h^2(s, Y_s)) \mathbb{1}_{\varepsilon/2 \leq |X_t - Y_t| \leq \varepsilon}] ds \\ &\quad + C \int_0^t \mathbb{E} [(\bar{h}_\varepsilon(s, X_s) + \bar{h}_\varepsilon(s, Y_s)) \mathbb{1}_{\varepsilon/2 \leq |X_t - Y_t| \leq \varepsilon}] ds. \end{aligned}$$

Denote

$$\alpha_k = \int_0^t \mathbb{E} [(h^2(s, X_s) + h^2(s, Y_s)) \mathbb{1}_{2^{-k-1} \leq |X_t - Y_t| \leq 2^{-k}}] ds.$$

Note that

$$\begin{aligned} \sum_k \alpha_k &\leq \int_0^t \mathbb{E} ((h^2(s, X_s) + h^2(s, Y_s))) ds \\ &= \int_0^t \int h^2(s, x) (u_X(dx, s) + u_Y(dx, s)) ds \leq C. \end{aligned}$$

Therefore $\alpha_k \rightarrow 0$ as $k \rightarrow +\infty$.

Denote similarly

$$\beta_k = \int_0^t \mathbb{E} ((\bar{h}_{2^{-k}}(s, X_s) + \bar{h}_{2^{-k}}(s, Y_s)) \mathbb{1}_{2^{-k-1} \leq |X_t - Y_t| \leq 2^{-k}}) ds.$$

Denote $J_i = \{k, [2^{-k-1}, 2^{-k}] \subset I_i\}$. Note that $|J_i| \geq \frac{1}{C} |\log b_i|$ (in fact, $|J_i| = \frac{|\log b_i|}{2 \log 2}$) and since \bar{h}_ε is fixed on $\varepsilon \in I_i$

$$\begin{aligned} \frac{1}{|J_i|} \sum_{k \in J_i} \beta_k &\leq \frac{1}{|J_i|} \int_0^t \int \bar{h}_{b_i}(s, x) (u_X(dx, s) + u_Y(dx, s)) ds \\ &\leq \frac{C^2}{b_i \phi(b_i^{-1})} \rightarrow 0 \quad \text{as } i \rightarrow \infty. \end{aligned}$$

Therefore $\beta_{n_k} \rightarrow 0$ as $k \rightarrow +\infty$ for some subsequence $n_k \rightarrow +\infty$. Consequently, since the sequence of functions L_ε is non increasing,

$$\sup_{t \in [0, T]} \mathbb{E}(L_\varepsilon(X_t - Y_t)) \rightarrow 0 \quad \text{as } \varepsilon \rightarrow 0.$$

On the other hand

$$\mathbb{E}(L_\varepsilon(X_t - Y_t)) \geq \mathbb{P}(|X_t - Y_t| > \varepsilon),$$

and by taking the limit $\varepsilon \rightarrow 0$, we deduce that for any $t \in [0, T]$

$$\mathbb{P}(|X_t - Y_t| > 0) = 0.$$

Therefore, $X_t = Y_t$ for all $t \in \mathbb{Q} \cap [0, T]$ almost surely, and since X_t and Y_t have a.s. continuous paths, we deduce that

$$\mathbb{P}\left(\sup_{t \in [0, T]} |X_t - Y_t| = 0\right) = 1,$$

which proves pathwise uniqueness.

5 Proof of Theorem 2.5

This proof follows exactly the same steps as the general multi-dimensional case given in Section 4. The only differences are the functionals used and accordingly we skip the other parts of the proof which are identical.

Technically the reason why the one dimensional case is so special is that $|x|$ is linear except at $x = 0$. We do not know whether this corresponds to a deeper more intrinsic difference between $d = 1$ and $d > 1$ or if the better results are in fact also true for $d > 1$.

5.1 Existence

For $d = 1$, we replace the functional $Q_{nm}^{(\varepsilon)}$ by

$$\tilde{Q}_{nm}^{(\varepsilon)}(t) = e^{-U_t^{n,m}} |X_t^n - X_t^m| \log \left(1 + \frac{|X_t^n - X_t^m|^2}{\varepsilon^2} \right),$$

for $U_t^{n,m}$ a nonnegative random variable satisfying $dU_t^{n,m} = \lambda_t^{n,m} dt$ with $\lambda_t^{n,m}$ an adapted process (measurable function of a continuous, adapted process) to be chosen later.

Note that $f(x) = |x| \log(1 + |x|^2/\varepsilon^2)$ satisfies

$$|f'(x)| \leq 4 \log \left(1 + \frac{|x|^2}{\varepsilon^2} \right) \quad \text{and} \quad |f''(x)| \leq \frac{C}{\varepsilon + |x|}.$$

Therefore by Itô's formula

$$\begin{aligned} \mathbb{E}(\tilde{Q}_{nm}^{(\varepsilon)}(t)) &\leq C + C \int_0^t \mathbb{E} \left(\frac{|\sigma(X_s^n) - \sigma(X_s^m)|^2}{\varepsilon + |X_s^n - X_s^m|} \right) ds + \frac{\eta(n, m)}{\varepsilon} \\ &\quad + \int_0^t \mathbb{E} \left(|X_s^n - X_s^m| \log(1 + |X_s^n - X_s^m|^2/\varepsilon^2) \right. \\ &\quad \left. \left(4 \frac{|F(s, X_s^n) - F(s, X_s^m)|}{|X_s^n - X_s^m|} - \lambda_t^{n, m} \right) \right) ds. \end{aligned}$$

The first term is treated identically as for the multi-dimensional case. The only difference here is that the careful choice of $\tilde{Q}_{nm}^{(\varepsilon)}$ improved the exponent of $|X_s^n - X_s^m|$ to 1 instead of 2 in the denominator. Therefore this term can be controlled with the $H^{1/2}(u_{n, m})$ norm of σ by using Lemma 3.3 instead of estimate (3.1).

The drawback is that the term with F must be dealt with differently. We introduce $\tilde{h} = M|\nabla F|$ s.t.

$$\int_0^T \int_{\mathbb{R}^d} \tilde{h}(t, x) (u_m(t, dx) + u_n(t, dx)) dt \leq C.$$

One poses

$$\lambda_t^{n, m} = 4 \left(\tilde{h}(t, X_s^m) + \tilde{h}(t, X_t^m) \right).$$

Therefore we deduce that

$$\sup_{t \leq T} \mathbb{E}(\tilde{Q}_{nm}^{(\varepsilon)}(t)) \leq C + \frac{\eta(n, m)}{\varepsilon}.$$

Using a similar method as in Theorem 2.4, we write for constants L and K to be chosen later

$$\begin{aligned} \mathbb{E}(|X_t^n - X_t^m|^p) &\leq \mathbb{E}(|X_t^n - X_t^m|^p; |X_t^n - X_t^m| \geq L) + \frac{1}{|\log \varepsilon|^{p/2}} \\ &\quad + \mathbb{P}(U_t^{n, m} \geq \log K) + L^p \mathbb{P} \left(|X_t^n - X_t^m| \geq \frac{1}{\sqrt{|\log \varepsilon|}}; U_t^{n, m} \leq \log K \right) \end{aligned}$$

Note that

$$\mathbb{E}(U_t^{n, m}) = \mathbb{E} \left(\int_0^t \lambda_s^{n, m} ds \right) \leq \int_0^t \tilde{h}(s, x) (u_n(s, dx) + u_m(s, dx)) ds \leq C.$$

Consequently

$$\mathbb{P}(U_t^{n,m} \geq \log(K)) \leq \frac{C}{\log K}.$$

In addition, for ε small enough,

$$\mathbb{P}\left(|X_t^n - X_t^m| \geq \frac{1}{\sqrt{|\log \varepsilon|}}; U_t^{n,m} \leq \log K\right) \leq \frac{K \mathbb{E}\tilde{Q}_{nm}^{(\varepsilon)}(t)}{2\sqrt{|\log \varepsilon|}}.$$

Therefore,

$$\mathbb{E}(|X_t^n - X_t^m|^p) \leq C \left(\frac{1}{L} + \frac{1}{|\log \varepsilon|^{p/2}} + \frac{1}{\log K} + \frac{L^p K \left(1 + \frac{\eta(n,m)}{\varepsilon}\right)}{\sqrt{|\log \varepsilon|}} \right).$$

Taking for example $\varepsilon = \eta(n,m)$, $K = |\log \varepsilon|^{1/8}$ and $L = |\log \varepsilon|^{1/8p}$, we deduce that

$$\sup_{t \in [0, T]} \mathbb{E}(|X_t^n - X_t^m|^p) \rightarrow 0, \quad \text{as } n, m \rightarrow +\infty.$$

The rest of the proof is similar.

5.2 Uniqueness

For simplicity, we assume here that $F = 0$. Otherwise it is necessary to introduce U_t as in the previous subsection but it is handled in exactly the same way.

We similarly change the definition of L_ε in

$$\tilde{L}_\varepsilon(x) = |x| \text{ if } |x| \geq \varepsilon, \quad \tilde{L}_\varepsilon(x) = 0 \text{ if } |x| \leq \varepsilon/2, \quad \|\nabla \tilde{L}_\varepsilon\|_{L^\infty} + \varepsilon \|\nabla^2 \tilde{L}_\varepsilon\| \leq C,$$

with C independent of ε .

Applying Itô's formula

$$\mathbb{E}(\tilde{L}_\varepsilon(X_t - Y_t)) \leq C \int_0^t \mathbb{E}\left(\mathbb{1}_{\varepsilon/2 \leq |X_t - Y_t| \leq \varepsilon} \frac{|\sigma(X_s) - \sigma(Y_s)|^2}{\varepsilon}\right) ds.$$

By using as before the assumptions, Lemma 3.3 and the corresponding definition of $H^{1/2}(u_X)$ and $H^{1/2}(u_Y)$, one deduces that

$$\mathbb{E}(\tilde{L}_\varepsilon(X_t - Y_t)) \rightarrow 0 \quad \text{as } \varepsilon \rightarrow 0.$$

This is slightly less strong than before ($L_\varepsilon \gg \tilde{L}_\varepsilon$ for $x \ll 1$) but still enough. In particular one has if $\alpha \geq \varepsilon$

$$\mathbb{P}(|X_t - Y_t| \geq \alpha) \leq \frac{1}{\alpha} \mathbb{E}(\tilde{L}_\varepsilon(X_t - Y_t)).$$

Therefore by taking $\varepsilon \rightarrow 0$, one still obtains that for any $t \in [0, T]$,

$$\mathbb{P}(|X_t - Y_t| > 0) = 0.$$

The conclusion follows in exactly the same way as before.

6 Proof of Prop. 2.9

We simply use the energy estimates. The computations below are formal but could easily be made rigorous by taking a regularization of σ, F and hence a and then pass to the limit.

$$\begin{aligned} \frac{d}{dt} \int u^\alpha(t, x) dx &= -\alpha(\alpha-1) \int u^{\alpha-1}(t, x) \nabla u(t, x) \cdot F(t, x) dx \\ &\quad -\alpha(\alpha-1) \int u^{\alpha-2}(t, x) \nabla u(t, x)^T a(t, x) \nabla u(t, x) dx \\ &\quad -\alpha(\alpha-1) \int u^{\alpha-1}(t, x) \sum_{1 \leq i, j \leq d} \frac{\partial u(t, x)}{\partial x_i} \frac{\partial a_{ij}(t, x)}{\partial x_j} dx. \end{aligned}$$

Note that by (2.8)

$$\int u^{\alpha-2}(t, x) \nabla u(t, x)^T a(t, x) \nabla u(t, x) dx \geq C \|\nabla u^{\alpha/2}\|_{L^2}^2.$$

On the other hand

$$\begin{aligned} \int u^{\alpha-1}(t, x) \nabla u(t, x) \cdot F(t, x) dx &\leq \|\nabla u^{\alpha/2}\|_{L^2} \|u^{\alpha/2}\|_{L^2} \|F\|_{L^\infty} \\ &\leq \frac{C}{4} \|\nabla u^{\alpha/2}\|_{L^2}^2 + C' \int u^\alpha(t, x) dx. \end{aligned}$$

And

$$\begin{aligned} \int u^{\alpha-1}(t, x) \sum_{1 \leq i, j \leq d} \frac{\partial u(t, x)}{\partial x_i} \frac{\partial a_{ij}(t, x)}{\partial x_j} dx &\leq \|\nabla u^{\alpha/2}\|_{L^2} \|u^{\alpha/2} \nabla a\|_{L^2} \\ &\leq \|\nabla u^{\alpha/2}\|_{L^2} \|\nabla a\|_{L^p} \|u^{\alpha/2}\|_{L^r}, \end{aligned}$$

with $1/2 = 1/p + 1/r$, which can be done since $p > d \geq 2$. Now by Sobolev embedding

$$\|u^{\alpha/2}\|_{L^r} \leq \left(\int u^\alpha dx \right)^{\theta/2} \|\nabla u^{\alpha/2}\|_{L^2}^{1-\theta},$$

for some $\theta \in (0, 1]$, precisely $1/r = 1/2 - (1 - \theta)/d$ or $(1 - \theta)/d = 1/p$, provided that $p > d$. In that case we immediately deduce that

$$\frac{d}{dt} \int u^\alpha(t, x) dx + \frac{C}{2} \int |\nabla u^{\alpha/2}|^2 dx \leq C'' \left(1 + \|\nabla a\|_{L^p}^{2/\theta} \right) \int u^\alpha dx.$$

This concludes the bound provided that

$$\int_0^T \|\nabla a\|_{L^p}^{2/\theta} < \infty,$$

which means that $\nabla a \in L_{t,loc}^q(L_x^p)$ with $1/q = \theta/2 = 1/2 - d/2p$. This exactly corresponds to the condition $2/q + d/p = 1$ with $p > d$.

Note that $p = d$ is critical here in the sense that the result could still hold in that case provided that the norm of ∇a is small enough with respect to the constant of ellipticity.

Finally we hence deduce that for any t and any $\alpha < \infty$

$$\|u(t, \cdot)\|_{L^\alpha} \leq \|u(t=0, \cdot)\|_{L^\alpha} \leq C,$$

with C independent of α since $u_0 \in L^1 \cap L^\infty$. This implies that $\|u(t, \cdot)\|_{L^\infty} \leq C$ and finishes the proof.

7 Proof of Prop. 2.14

We are going to prove this result under the assumptions of Corollary 2.11. The other cases are completely similar.

Fix a complete filtered probability space $(\Omega, (\mathcal{F}_t)_{t \geq 0}, \mathbb{P})$ equipped with a r -dimensional standard Brownian motion W . Fix also $u_0 > 0$ in $L^1 \cap L^\infty$. Then, by Corollary 2.10, on the probability space $(\mathbb{R}^d \times \Omega, (\mathcal{B}(\mathbb{R}^d) \otimes \mathcal{F}_t)_{t \geq 0}, u_0(x) dx \mathbb{P}(d\omega))$, there is strong existence and pathwise uniqueness for (1.1) with $\xi(x, \omega) = x$. We deduce that strong existence for almost every deterministic initial condition holds for (1.1) on $(\Omega, (\mathcal{F}_t)_{t \geq 0}, (W_t)_{t \geq 0}, \mathbb{P})$.

For uniqueness, the two key points are

- first, that $u \in L^\infty$, $\sigma \in H^1(u)$ and $F \in W^{\phi, weak}(u)$ (instead of uniform bounds for u_n only as in Theorem 2.4);

- second, that we are always in cases where uniqueness in law is known for *all* initial conditions in (1.1), and in particular for all deterministic initial conditions.

For all x such that strong existence holds for (1.1) with $\xi = x$, let X_t^x and \hat{X}_t^x be two strong solutions of (1.1) such that $X_0^x = \hat{X}_0^x = x$ a.s. Repeating the proof of Lemma 4.1, we have

$$\begin{aligned} \mathbb{E} \log \left(1 + \frac{|X_t^x - \hat{X}_t^x|^2}{\varepsilon^2} \right) &\leq C \int_0^t \mathbb{E} \left[M |\nabla \sigma|(s, X_s^x)^2 + M |\nabla \sigma|(s, \hat{X}_s^x)^2 \right] ds \\ &\quad + C \int_0^t \mathbb{E} \left[(|F| + M_{1/\varepsilon} \nabla F)(s, X_s^x) + (|F| + M_{1/\varepsilon} \nabla F)(s, \hat{X}_s^x) \right] ds \end{aligned}$$

By uniqueness in law, for all $s \geq 0$, X_s^x and \hat{X}_s^x have the same distribution, and so

$$\begin{aligned} \mathbb{E} \log \left(1 + \frac{|X_t^x - \hat{X}_t^x|^2}{\varepsilon^2} \right) &\leq C \int_0^t \mathbb{E} \left[((M |\nabla \sigma|)^2 + |F| + M_{1/\varepsilon} \nabla F)(s, X_s^x) \right] ds. \end{aligned}$$

Let us denote by $M_t^\varepsilon(x)$ the integral in the r.h.s. Note that the l.h.s. may not be a measurable function of x , but $M_t^\varepsilon(x)$ is, and choosing ϕ as in the proof of Corollary 1.1

$$\begin{aligned} \int_{\mathbb{R}^d} M_t^\varepsilon(x) u_0(x) ds &= \int_0^t \int_{\mathbb{R}^d} ((M |\nabla \sigma|)^2 + |F| + M_{1/\varepsilon} \nabla F)(s, x) u(s, dx) ds \\ &\leq C \left(1 + \frac{|\log \varepsilon|}{\varepsilon \phi(\varepsilon^{-1})} \right). \end{aligned}$$

Now, copying the proof of Lemma 4.2,

$$\mathbb{E}(|X_t^x - \hat{X}_t^x|) \leq C \left[\sqrt{\varepsilon} + \frac{1}{L} + \frac{LM_t^\varepsilon(x)}{|\log \varepsilon|} \right]$$

Let us denote by $N_t^\varepsilon(x)$ the r.h.s. Choosing $L = \left(\frac{1}{|\log \varepsilon|} + \tilde{\eta}(\varepsilon) \right)^{-1}$ with $\eta(\varepsilon) = (\varepsilon \phi(\varepsilon^{-1}))^{-1}$, we obtain

$$\int_{\mathbb{R}^d} N_t^\varepsilon(x) u_0(x) ds \leq C \left(\sqrt{\varepsilon} + \sqrt{\frac{1}{|\log \varepsilon|} + \tilde{\eta}(\varepsilon)} \right).$$

Since the r.h.s. converges to 0 when $\varepsilon \rightarrow 0$, there exists a sequence $\varepsilon_k \rightarrow 0$ such that $N_t^{\varepsilon_k}(x) \rightarrow 0$ for almost all x . The diagonal procedure then shows the existence of a subsequence $\varepsilon'_k \rightarrow 0$ such that $N_t^{\varepsilon'_k}(x) \rightarrow 0$ for almost all x and for all t in a dense denumerable subset of $[0, T]$. Since the paths of X^x and \hat{X}^x are continuous, we deduce that pathwise uniqueness holds for almost all $x \in \mathbb{R}^d$.

Appendix: Sketch of the proof of Corollary 1.1

The only thing left to prove after Theorem 2.4 is: Assume $u \in L_{t,loc}^{q'}(L_x^{p'}(\mathbb{R}^d))$ then show that, for some super linear ϕ ,

$$\|\sigma\|_{H^1(u)} \leq C \|\nabla\sigma\|_{L_{t,loc}^{2q}(L_x^{2p})}, \quad \|F\|_{W^{\phi,weak}(u)} \leq C \|\nabla F\|_{L_{t,loc}^q(L_x^p)}.$$

From the fact that the maximal operator M is bounded on L^p , $p > 1$, then this is straightforward for σ (as $2p \geq 2 > 1$). It is also the case for F whenever $p > 1$ (taking $\phi(M) = M \log M$).

Therefore the key point is how to prove that for F when $p = 1$.

Now fix L and denote

$$h(t, x) = M_L \nabla F = C \sqrt{\log L} + C \int_{B_1(x)} \frac{|\nabla F(t, z)| \mathbb{1}_{|\nabla F| \geq \sqrt{\log L}} dz}{(L^{-1} + |x - z|) |x - z|^{d-1}},$$

where $B_1(x)$ is the ball of radius 1 centered at x . As $p' = \infty$, for almost any fixed t , $u(t, \cdot) \in L^1 \cap L_x^\infty$ and hence

$$\begin{aligned} \int h(t, x) u(t, x) dx &\leq C \sqrt{\log L} + C \|u(t, \cdot)\|_{L^\infty} \\ &\quad \int \int_{B_1(x)} \frac{|\nabla F(t, z)| \mathbb{1}_{|\nabla F| \geq \sqrt{\log L}} dz}{(L^{-1} + |x - z|) |x - z|^{d-1}} dx \\ &\leq C \sqrt{\log L} + C \log L \|u(t, \cdot)\|_{L^\infty} \|\nabla F(t, \cdot) \mathbb{1}_{|\nabla F| \geq \sqrt{\log L}}\|_{L^1}, \end{aligned}$$

by Fubini's theorem.

Therefore integrating now in time, by Hölder's estimates

$$\int_0^T \int h(t, x) u(t, x) dx dt \leq C \sqrt{\log L} T + C \log L \|\nabla F \mathbb{1}_{|\nabla F| \geq \sqrt{\log L}}\|_{L_t^q(L_x^1)}.$$

Now if $\nabla F \in L_t^q(L_x^1)$ then de la Vallée Poussin classical integrability result means that there exists a super linear ψ s.t.

$$\|\psi(\nabla F)\|_{L_t^q(L_x^1)} < \infty.$$

Consequently

$$\int_0^T \int h(t, x) u(t, x) dx dt \leq C \sqrt{\log L} T + C \frac{(\log L)^{3/2}}{\psi(\sqrt{\log L})}.$$

We may conclude that $\|\nabla F\|_{W^{\phi, weak}}$ is bounded for ϕ defined by

$$\frac{L}{\phi(L)} = \frac{C \sqrt{\log L}}{\log L} + \frac{C \sqrt{\log L}}{\psi(\sqrt{\log L})},$$

which is hence also super linear.
